

React

Pearce Campbell
Sebastian Vargas
Bryce Schumacher

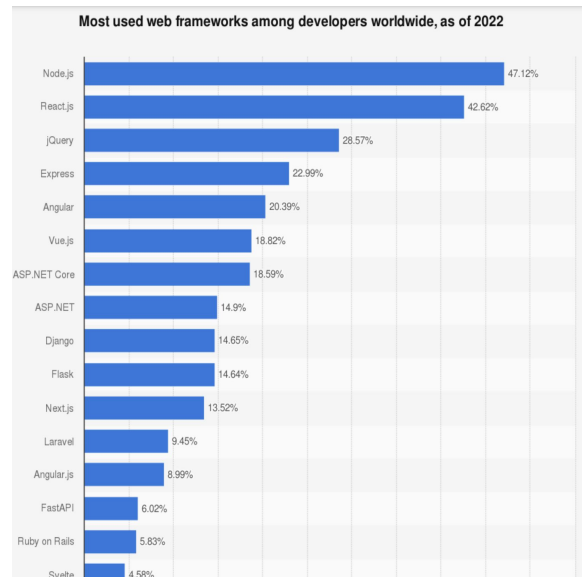

What is React?

- React, React.js, ReactJS
- Created by Facebook
- JavaScript Framework made for creating sophisticated frontend code
- Allows us to write html code within our javascript files
- As you develop your app, it will change in real time

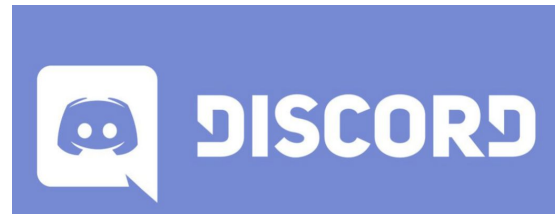

Why use React? What are the benefits?

- React can be easily modularized
- Massive library support
- Vast Open source community
- Some companies that use React are Instagram, Netflix, New York Times, Airbnb, and Discord

Companies That Use React

What is the DOM vs Virtual DOM?

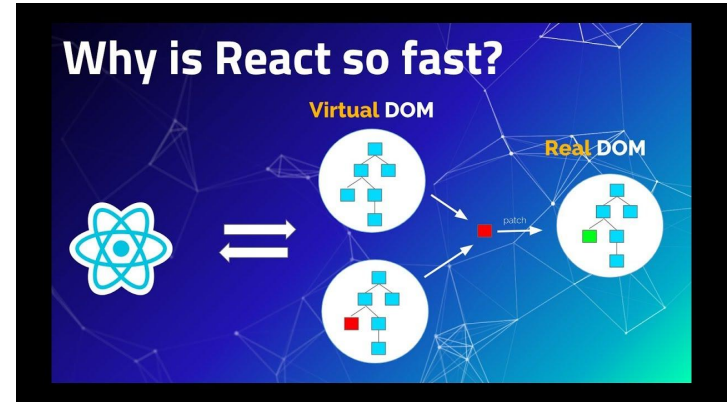

- DOM stands for Document Object Model
- The Document Object Model is a hierarchy of structure given to components within any HTML page and has a tree structure that essentially follows the parent child structure of most trees and graphs, and example of which is the Table component

What is the Virtual DOM?

- Key aspect of react is the use of the Virtual DOM
- Creates representations of Actual DOM
- Updates very quickly
- Uses little resources
- Allows for efficient testing before implementation

React Components

- Components are the core building blocks of React
- A component lets a programmer split their UI into several independent parts
- A component can be defined by simply writing a Javascript function or class
- When using a class method, a render() method is required.
- A return statement will return JSX elements

```
class App extends React.Component {  
  render() {  
    console.log("This is javascript");  
    return (  
      <div>This is JSX/HTML </div>  
    )  
  }  
}
```

Component Specifics

```
✓ class Button extends React.Component {  
✓   render() {  
✓     return (  
       <button>Button</button>  
     );  
   }  
}  
  
export default Button;
```

```
class App extends React.Component {  
  render() {  
    console.log("This is javascript");  
    return (  
      <div>  
        <Button />  
        <Button />  
      </div>  
    )  
  }  
}  
  
<App />
```

Props vs. State

Props:

Things that don't change

State:

Things that could change

Props

```
class App extends React.Component {  
  render() {  
    return (  
      <div>  
        <Child props_example={"hello 1"}/>  
        <Child props_example = {"hello 2"}/>  
      </div>  
    );  
  }  
}
```

```
class Child extends React.Component {  
  render() {  
    return (  
      <h1>{this.props.props_example}</h1>  
    );  
  }  
}
```

localhost:3000

hello 1

hello 2

State

```
class App extends React.Component {  
  constructor(props) {  
    super(props)  
    this.state = {name: 'Andrew'}  
    this.clickEvent = this.clickEvent.bind(this);  
  }  
  
  clickEvent() {  
    this.setState({name: 'Jack'})  
  }  
  
  render() {  
    return (  
      <div>  
        <h1 onClick={this.clickEvent}>Name: {this.state.name}</h1>  
      </div>  
    );  
  }  
}
```

← → ↻ ⓘ localhost:3000

Name: Andrew

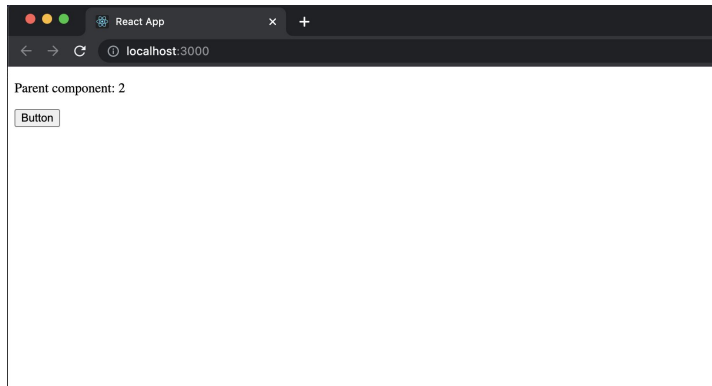

State cont.

```
class App extends React.Component {
  constructor(props) {
    super(props);
    this.state = {
      counter: 0
    }
    this.clickEvent = this.clickEvent.bind(this);
  }

  clickEvent() {
    let curr_count = this.state.counter;
    this.setState({counter: curr_count+1});
  }

  render() {
    return (
      <div>
        <p>Parent component: {this.state.counter}</p>
        <Button clickerEvent={this.clickEvent}/>
      </div>
    );
  }
}
```

```
class Button extends React.Component {
  render() {
    return (
      <button onClick={this.props.clickerEvent}>Button</button>
    );
  }
}
```

How it Relates to the Course

- Callback Functions
- Abstract Data types
- Higher Order functions

Callback Functions

```
class App extends React.Component {
  constructor(props) {
    super(props)
    this.state = {style: 'none'}
    this.uncover = this.uncover.bind(this);
  }

  uncover() {
    if (this.state.style === "none") {
      this.setState({style: "inline"})
    }
    else {
      this.setState({style: "none"})
    }
  }

  render() {
    return (
      <div>
        <Button uncover={this.uncover} />
        <h1 style={{display: this.state.style}}>Hello there</h1>
      </div>
    );
  }
}
```

```
class Button extends React.Component {
  render() {
    return (
      <button onClick={this.props.uncover}>Button</button>
    );
  }
}

export default Button;
```

Callback Demo

Abstract Data Types

- React components are abstract data types
- They are instantiated, and defined by the React component notation

Thanks for watching!
